CafeOBJ Commands Quick Reference

(for interpreter version 1.4.8)

Notation

Keywords apper in type setter face, when presented in the form like 'x(yz)' it means the keyword 'xyz' can be abbreviated to 'x'. '[something]' means 'something' is optional. I is used for listing alternatives. Slanted face, e.g., variety is used when it varies (a metavariable) or is an expression of some language. For example, modexp is for module expressions and term is for terms (you should know what these are); others should easily be understood by their names and/or from the context.

Starting CafeOBJ interpreter

To enter CafeOBJ, just type its name: cafeobj

'cafeobj -help' will show you a summary of command options.

Leaving CafeOBJ

q(uit) exits CafeOBJ.

Getting Little Help

Typing? at the top-level prompt will print out a list of whole top-level commands.

Escape

There would be a situation that you hit return expecting some feedback from the interpreter, but it does not respond. This occurs when the interpreter expects some more inputs from you thinking preceding input is not yet syntactically complete. If you encounter this situation, and you don't know what the interpreter expects, simply type in esc(escape key) and return, then it will immediately be back to you discarding preceding input and makes a fresh start.

Rescue

Occasionally you may meet a strange prompt CHAOS>> after some error messages. This happens when the interpreter caused some internal errors and could not recover from it. Try typing :q, this may resume the session if you are lucky.

Sending interrupt signal (typing C-c from keyboard, or if you are in Emacs, some key sequence specific to the *mode* you are in) forces the interpreter to break into underlying Lisp, and you will see the same prompt as the above. This might be useful when you feel the interpreter get confused. :q also works for returning to CafeOBJ interpreter from Lisp.

Setting Switches

Switches are for controlling the interpreter's behaviour in several manner. The general form of setting top-level switch is:

set switch value

In the following, the default value of a switch is shown underlined.

In the following, the default value of a switch is shown underlined.			
	switch	value	what?
	***		– switches for rewriting
	trace whole	on <u>off</u>	trace top-level rewrite step
	trace	on <u>off</u>	trace every rewrite step
	step	on <u>off</u>	stepwise rewriting process
	memo	<u>on</u> off	enable term memoization
	clean memo	on <u>off</u>	clean up term memo table
			before normalization
	stats	<u>on</u> off	show statistics data after reduction
	rwt limit	number	maximum number of rewriting
	stop pattern	[term] .	stop rewriting when meets
	mel sort	on <u>off</u>	compute result sort with
			sort membership predicates
	reduce conditions	on <u>off</u>	reduce conditional part in
			apply command
	verbose	on <u>off</u>	set verbose mode
	exec trace	on <u>off</u>	trace concurrent execution
	exec limit	number	limit maximum number of
			concurrent execution
	exec normalize	<u>on</u> off	reduce term before and after
			each transition
	exec all	<u>on</u> off	find all solutions of $=(*)=>$
	***		 switches for system's behaviour
	include BOOL	<u>on</u> off	import BOOL implicitly
	incude RWL	<u>on</u> off	import RWL implicitly
	include FOPL-CLAUSE	<u>on</u> off	import FOPL-CLAUSE implicitly
	auto context	on <u>off</u>	change current context in automatic
	auto reconstruct	on <u>off</u>	perform automatic reconstruction
	_		of modules if it is inconsistent
	reg signature	on <u>off</u>	regularize module signature
			in automatic
	check regularity	on <u>off</u>	perform regularity check of
			signature in automatic
	check compatibility	on <u>off</u>	perform compatibility check of TRS in automatic
	check builtin	anlaff	
	check builtin	<u>on</u> off	perform operator overloading check with built-in sorts
	select term	on off	system selects a term from
	Select telm	0111011	ambiguously parsed terms
	quiet	on off	system mostly says nothing
	quiet	0111011	- show/display options
	all axioms	on off	print all axioms in
	dii dalomb	0111011	"sh(ow) modexp" command
	show mode	:cafeobj	set syntax of printed modules
	Direct mede	l:chaos	or views
	show var sorts	on off	print variables with sorts
	print mode	:normal	set term priting form
	F	:fancy	*** *****
		:tree	
		:s-expr	
	***	r	- miscellaneous settings
	libpath	pathname	set file search path
	print depth	number	maximum depth of terms
			to be printed
	accept =*= proof	on <u>off</u>	accept system's automatic
	-	_	proof of congruency of =*=

The default value of pathname of set libpath command is '\$cafeob-

jhome/lib, \$cafeobjhome/exs', where '\$cafeobjhome' varies depending on the installation options of your interpreter. Normally, it is /usr/local/lib/cafeobj1.4.

The default value of *number* in 'set rwt limit' command is 0 meaning no limit counter of rewriting is specified.

Omitting term in set stop pattern sets the stop pattern to empty, i.e., no term will match to the pattern.

Examining Values of Switches

show switch print list of available switches

with their values

show switch switch print out the value of the

specified switch

Setting Context

select modexp

This sets the context of the interpreter (current module) to the module specified by modexp. It must be written in single line. When you type in *modexp*, the ';<newline>' treated as a line continuation (that is, it is effectively ignored), so that you can type in multiple lines for long module expressions. Note that one or more blank characters are required before;.

Inspecting Module

sh(ow) and desc(ribe) commands print information on a module. In the sequel, we use a meta-variable show which stands for either sh(ow) or desc(ribe). Most of the cases, giving desc(ribe) for show gives you more detailed information.

show modexp prints a module *modexp*. giving '."

as modern shows the current module

show sorts [modexp] prints sorts of modexp prints operators of modexp show ops [modexp] show vars [modexp]prints variables of modexpshow params [modexp] prints parameters of modexp

show subs [modexp]prints direct submodules of modexpshow sign [modexp] prints sorts and ops combined

modexp must be given in an one line. The same convention for long module expressions is used as that of select command (see Setting Context above.) If the optional [modexp] is omitted, it defaults to the current module. Optionally supplying all before sorts, ops, axioms, and sign, i.e., desc all ops for an instance) makes printed out information also include imported sorts, operators, etc. otherwise it only prints own constructs of the modexp.

The following show commands assume the current module is set to some module.

show sort sort prints information on sort sort prints information on operator operator show op operator

For inspecting submodules or parameters, the following show com-

mands are useful:

prints information on the parameter show param argname prints information on the nth direct show sub n

submodule

argname can be given by position, not by name.

You can see the hierarchy of a module or a sort by the follwing sh(ow) commands:

sh(ow) module tree modexpprints pictorial hierarchy of module.

specifying . as modexp shows the hierarcy of the current module prints hierarchy of sort pictorially

Evaluating Terms

sh(ow) sort tree sort

red(uce) [in modexp :] term . exec(ute) [in modexp :] term .

reduce reduces a given term term in the term rewriting system derived from modexp. execute is similar to reduce, but it also considers axioms given by transition declarations. In both cases, omitted 'in modexp:' defaults to the current module.

The result term of reduce and execute is bould to special variables \$\$term and \$\$subterm (see the next section).

Let Variables and Special Variables

let let-variable = term

let-variable is an indentifier. Assuming the current module is set, let binds let-variable to the given term term. Once set, let-variable can be used wherever term can apper.

You can see the list of let bidings by:

sh(ow) let

There are two built-in special variables in the system:

bound to the result term of reduce, execute, \$\$term

parse, or start commands.

bound to the result of choose command \$\$subterm

Let variales and special variables belongs to a context, i.e., each context has its own let variables and special variables.

Inspecting Terms

parse [in modexp :] term.

parse parses given term term in the module modexp (if omitted, parses in the current module) and prints the result. The result is bound to special variables \$\$term and \$\$subterm.

The following sh(ow) command assumes the current module, and prints the term.

sh(ow) term [let-variable] [tree]

let-variable can be a name of let-variable, \$\$term or \$\$subterm, if omitted the term bound to \$\$term is printed. If optional tree is supplied, it prints the term tree structure.

Opening/Closing Module

open modexp opens module modern

close the currently opening module

Opening module can be modified, i.e., you can declare new sorts, operators, axioms. You can open only one module at a time.

Applying Rewrite Rules

Start The initial target (entire term) is set by start command. start term.

This binds two special variables \$\$term and \$\$subterm to term.

 $\ensuremath{\mathbf{Apply}}$ apply command applies actions to (subterm of) \$\$term.

apply action range selection

You specify an action by *action*, and it will be applied to the target (sub)term specified by *selection*.

range is either within or at: within means at or inside the (sub)term specified by the selection, and at means exactly at the selection.

Action action can be the followings:

red(uction) reduce the selected term
exec execute the selected term
print print the selected term

rule-spec apply specified rule to the selected term

Rule-Spec rule-spec specifies the rule with possibly substitutions being applied, and given by

 $[+ \ | \ -][modexp].rule-name [substitutions]$

The first optional '+ | -' specifies the direction of the rule; left to right(if + or omitted) or right to left (if -).

A rule itself is specified by '[modexp].rule-name]'. This means the rule with name rule-name of the module modexp (if omitted, the current module). rule-name is either a label of a rule or a number which shown by sh(ow) rules command (see Showing Available Rules below.)

substitution binds variables that apper in the selected rule before applying it. This has the form

with variable = term , ...

Showing Available Rules To see the list of the rewrite rules, use sh(ow) [all] rules

The list of the (all, i.e., includes imported rules if the optional all is supplied) available rules are printed with each of which being numbered. The number can be used for *rule-name* (see above).

Selection selection is a sequence of selector separated by keyword of specifying (sub)term of **\$\$term**:

 $selector \{ of selector \} \cdots$

selector description

term the entire term (\$\$term)

top ditto

subtermselects \$subterm $(number \cdots)$ selects by position

[number .. number] by range in flattened term structure { number , \cdots } subset in flattened term structure

Step by Step Subterm Selection choose command selects a subterm of \$\$subterm and reset the \$\$subterm to the selected one.

choose selector

Matching Terms

 ${\tt match}\ term_spec\ {\tt to}\ pattern$

term_spec specifies the term to be matched with pattern:

 term_spec
 description

 term
 \$\$term

 top
 ditto

 subterm
 \$\$term

 it
 ditto

 term
 ordinal term

pattern description

[all][+ \mid -] rules \quad match with available rewrite rules

rm match with specified term

Stepper

If the switch step is set to on, invoking reduce or execute command runs into the term rewriting stepper. The stepper has its own command interpreter loop, where the following stepper commands are avilable:

? print out available commands.

c(ontinue) continue rewriting without stepping q(uit) leave stepper continuing rewrite

a(bort) abort rewriting

r(rule) prints current rewrite rule s(ubst) prints substitution

1(imit) prints rewrite limit counter

prints stop pattern
stop [term] set (unset) stop pattern
rwt [number] set (unset) rwrite limit counter

You can also use families of ${\tt sh(ow)(desc(ribe))}$ and ${\tt set}$ commands in stepper.

Reading In Files

 ${\tt input} \ \mathit{file} \\ {\tt read in CafeOBJ program from } \mathit{file} \\$

provide feature provide the feature require feature [file] require feature

Save and Restore

 save file
 save definitions of modules and views to file

 restore file
 restore definitions of modules and views

 reset
 recover definitions of built-in modules

 full-reset
 reset system to initial status

 save-system file
 save image of the interpreter to file

Protecting Your Modules

protect modexp prevent the module from redefinition unprotect modexp allow moudle to be redefined

Little Semantic Tools

check reg(ularity) [modexp]

reports the result of regularity

check of module

 ${\tt check\ comat(ibility)}\ [{\it modexp}$

reports the result of compatibility

check of the module

For both commands, omitted modexp will perform the check in the current module.

The following check command assumes the current module:

check laziness [operator]

This checks strictness of operator. If operator is omitted all of the operators declared in the current modules are checked.

TRAM Compiler Interface

tram compile [modexp]

This compiles module *modexp* to Term Rewriting Abstract Machine. If *modexp* is omitted, it defaults to the current module. *modexp* must be given in an line. You can supply multiple lines by using ';<new-line>'.

To evaluate term in compiled module, use the following:

 $\mathtt{tram}\ \mathtt{exec}\ [\mathtt{in}\ modexp:]\ term$

Omitting 'in *modexp*:' means the evaluation is performed in the current module. If the module *modexp* is not yet compiled, this compiles it implicitly, then perform the evaluation.

Miscellany

1s pathname list contents of directories

 ${\tt cd}\ pathname$ change working directory of the interpreter

pwd prints working directory
! command fork shell command

ev lisp evaluate lisp expression lisp printing the result

evq lisp evaluate lisp expression lisp
